Single- and Multi-circuit Pumps
for Circulating and Hydrostatic Lubrication
as Gear and Vane Pump Units, Reservoir Units

The pump units specified in this leaflet are lubricant delivery pumps without pressure relief fixtures and are designed for continuous operation in circulating and hydrostatic lubrication systems.

Units with one to twenty lubrication circuits are available.

Multicircuit gear pumps ensure a uniform delivery rate to individual feed lines and lubrication points against varying resistances.

These pump units may also be used for hydraulic tasks to the extent permitted by the pressure and viscosity ranges stated in the tables on the following pages.

The drive is provided by a three-phase motor designed for arated voltage of 230/400 V to DIN IEC 38. Specify special voltages, if required, when ordering.

The indicated delivery rate refers to an operating viscosity of 140 mm²/s at a back pressure of p = 5 bars.

The permissible pressure and delivery rates vary with the viscosity. Pay attention to the respectively permissible viscosity!

When using oils with viscosities outside the indicated permissible ranges (spindle oils and highly viscous oils), please ask for further information. Please note that even standard oils may become extremely thin-bodied or highly viscous due to changes in temperature.

Ambient temperature max. +40 °C
Lubricant temperature 0 °C to +80 °C
Single- and Multicircuit Pumps

Single-circuit flangemounted units with integral cast valve chambers – Circulating lubrication

Type M units for mounting separately from oil reservoir

Type MF units for flange-mounting on oil reservoir

Use a special sealed pump for horizontal flange-mounting of the unit beneath the oil level.

Explanation of the hydraulic function

Both versions (M and MF) have the same hydraulic function.

Oil is sucked in at S and flows through the pressure duct in direction P. The oil pressure closes valve V and opens valve E3 against spring tension. If air is entrained (due to low oil level in the reservoir), valve V remains open and bleeds the air or the air-intermixed oil into the return duct (see circle (o) marking the flow in directions R1 and R2 respectively). Valve C1 allows the excess-pressure oil to flow into the return duct (see cross (+) marking).

Explanation of the structural differences

With type M the long screw plug D1 blocks flanged port R2 of the return duct. The oil returning from the valves V and C1 flows via R1 through a line of tubing into the separate oil reservoir (see Fig. 1 and 2).

With type MF, the short screw plug D2 leaves flanged port R2 open – contrary to D1 with type M – and a plug seals external port R1. Flanged port R2 of the return duct discharges directly into the reservoir without any threaded connections (see Fig. 4 and 5).

Two-circuit flange-mounted units, valveless – Circulating lubrication

Units for mounting separately from oil reservoir or for flange-mounting on oil reservoir

When a third gear is added to the pump, these units have a second delivery circuit (see P2).

Unlike single-circuit units M and MF described on page 2, these pumps are valveless (see changes in C2 and E4).

Since there is no internal oil return, there are no structural differences of the kind specified on page 2 for M and MF.

A special sealed pump must be used for horizontal flange-mounting of the unit in a position beneath the oil level (see Fig. 3 on page 2).

For two-circuit units complete with reservoir see page 13.

Units without foot have the same dimensions.

The dimensions and data indicated for the electric motors are recommended values and can be different in the case of individual manufacturers.

When special pressure relief and safety valves are used, the single-circuit pump units specified here may also be used for intermittently operated distributor systems if the units specially designed for this purpose, specified in leaflet 1-1202-EN do not meet the quantity requirements.

Special notes!

1. Actual rotation of the motor must be the same as in the drawing to the left.
2. When units are flange-mounted on the oil reservoir in a horizontal position, make sure the pump is not lower than the oil level (intermediate flange is not sealed.)
3. If the unit is mounted separately from the oil reservoir, the suction side of the pump (S) may be connected to a higher oil reservoir (max. 2000 mm).

Please pay attention to further notes on page 6.

Any delivery ports not required must not be blanked off. The oil delivered through these ports must be returned to the oil reservoir.

Hydrostatic lubrication

In the case of hydrostatic bearings, the oil pressure appropriate to the bearing’s load-carrying capacity is generated in pumps outside the bearing, the oil being delivered at this pressure to the bearing recesses. From there, the oil escapes through the bearing gaps.

The smaller the output per circuit, the lower the oil viscosity and the greater the pump pressure, and the more the flow rates of the circuit will differ from each other.

The pressure difference within a multicircuit pump can be kept very small by utilizing a priming pump, which also helps to provide for uniform delivery rates.

The total capacity of the multicircuit pump and the recess pressure required per delivery circuit, with due consideration given to the permissible difference in pressures, is decisive when it comes to the choice of this priming pump.

By choosing the appropriate recess size, it is possible to keep the recess pressure within the desired limits. A medium-viscosity oil should be selected unless special tasks are involved.

With bearings that are subject to great pressure fluctuations, a proportioning pressure valve can be used to adapt the priming pressure to the particular pressure of a characteristic recess.

When a priming pump is used, a suitable filter can be installed in the priming pump’s pressure line.
Single- and Multicircuit Pumps

Four-circuit units
for operation with separate priming pump

Unlike the multicircuit pumps specified on pages 7 and 8, the pumps shown in figures 18-22 are operated as distribution pumps.

They require a priming pump, which is operated separately.
(For a selection of priming pumps, see the tables below.)

It is advisable to filter the oil upstream of the distribution pump inlet.

Type of enclosure IP 54, DIN 40050
Pay attention to direction of rotation, marked by arrow.

The dimensions and data indicated for the electric motors are recommended values and can be different in the case of individual manufacturers.

Any delivery ports not required must not be blanked off. The oil delivered through these ports must be returned to the oil reservoir.
Pump units are also available mounted on reservoirs.

Capacities of reservoirs: 3, 6, 15, 50, 100, 200, 400 liters.

Pump units complete with reservoir may be comprised of the following:

- one or more pump units
- directional or safety valves
- pressure relief valves (when used for intermittent lubrication)
- filters
- return oil connections (R)
- oil level sight glass
- float switch (WS)
- cooling units
- pressure switches
- thermometers
- flow monitors
- pressure gauges
- pressure gauge protection valves
- pressure gauge selector valves (5 or 10 connections)
- heating elements

1) The order number must be completed with the selected single- or two-circuit unit as detailed on pages 3 and 5.

**Order examples:**

Single-circuit gear pump unit MF2
with 6 liter plastic reservoir,
Order No.: MF2-2000-KW6

Two-circuit gear pump unit M202
with 15 liter metal reservoir,
Order No.: M202-BW16
3-fold reservoir unit serving as a supply unit for a printing machine

The gerotor pump (delivery rate 9 l/min) is used to supply the gears in a circulating lubrication system and to provide for dissipation of heat at the same time.

The gerotor pump (delivery 12.5 l/min) sucks the hot oil off again and feeds it back into the supply unit’s reservoir via a cooler. That makes sure that appropriately cooled oil is always available for the gear circuit.

Another MF5 unit is used to supply the cams with corresponding amounts of oil at specified intervals by way of piston distributors.
The Power of Knowledge Engineering

Drawing on five areas of competence and application-specific expertise amassed over more than 100 years, SKF brings innovative solutions to OEMs and production facilities in every major industry worldwide. These five competence areas include bearings and units, seals, lubrication systems, mechatronics (combining mechanics and electronics into intelligent systems), and a wide range of services, from 3-D computer modelling to advanced condition monitoring and reliability and asset management systems. A global presence provides SKF customers uniform quality standards and worldwide product availability.

Important information on product usage

All products from SKF may be used only for their intended purpose as described in this brochure and the operating instructions. If operating instructions are supplied together with the products, they must be read and followed.

Not all lubricants can be fed using centralized lubrication systems. SKF can, on request, inspect the feedability of the lubricant selected by the user in centralized lubrication systems. Lubrication systems and their components manufactured by SKF are not approved for use in conjunction with gases, liquefied gases, pressurized gases in solution, vapors or such fluids whose vapor pressure exceeds normal atmospheric pressure (1 013 mbar) by more than 0.5 bar at their maximum permissible temperature.

In particular, we call your attention to the fact that hazardous materials of any kind, especially the materials classified as hazardous by EC Directive 67/548/EEC, Article 2, Para. 2, may only be filled into SKF centralized lubrication systems and components and delivered and/or distributed with the same after consultation with and written approval from SKF.
